ABSTRACT
Placenta accreta spectrum, formerly known as morbidly adherent placenta, refers to the range of pathologic adherence of the placenta. Placenta accreta spectrum is a complicated pregnancy linked to significant maternal and fetal health risks. There should be high suspicion for placenta accreta spectrum in previous cesarean delivery to early diagnose and treat the condition. Placenta accreta spectrum can be classified into three groups: placenta accreta, where the villi attach to the myometrium; placenta increta, where the villi invade the myometrium; and placenta percreta, where the villi penetrate the entire thickness of the myometrium.1, 2 We report a case of placenta percreta who underwent cesarean hysterectomy while working in a resource-limited setting of rural Nepal.

Keywords: obstetrics, obstetric emergency, placenta percreta, uterine rupture, rural surgery

CASE REPORT

We present to you a case of 37 years old female, G3P1L1A1 at 25 weeks of gestation with previous LSCS, who presented to Dolakha Hospital, Dolakha with complaints of abdominal pain for 3 days, with increased intensity over the past 6 hours. Also reports decreased fetal movement for the past 6 hours and dizziness for the past 3 hours. On examination, the patient was in a state of hypovolemic shock. Her abdomen was distended about 26 weeks size with tenderness and guarding present in the epigastrium. Bed-side ultrasound showed fluid collection in the abdominal cavity and absent fetal cardiac activity. Placenta was fundally placed. Fluid resuscitation was done and the patient underwent emergency exploratory laparotomy. Per operatively, gross hemoperitoneum was noted in the abdominal cavity along with clots of about 2000 ml (fig. 2). A ruptured uterus at fundus (fig. 1) with ongoing bleeding was present. Placenta was adherent to the uterine wall and penetrated the serosa at the site of rupture (fig. 1). Lower Uterine Segment was not well formed and the urinary bladder was adherent to the previous cesarean scar. A single dead fetus weighing 800gms was delivered via low transverse uterine incision and a subtotal hysterectomy was subsequently performed with placenta in situ. The uterus along with the placental tissue was sent for histopathological evaluation. A total of about 1400ml of fresh whole blood was transfused operatively and post-operatively. Patient needed ionotropic support on 1st post-operative day. The patient’s condition improved on the following day, and inotrope was gradually tapered off. After further discussion with the patient party, the patient was referred to TUTH on their request.

DISCUSSION

Placenta accreta occurs in approximately 1:1000 deliveries with a reported range from 0.04% rising up to 0.9%.

Numerous hypotheses have been put forward to elucidate the causes and mechanisms behind the occurrence of PAS. The primary theory suggests that a medically induced issue in the endometrium-myometrium boundary results in the failure of typical decidualization at the location of a uterine scar. This, in turn, allows for unusually deep infiltration of trophoblast cells. The decidua, which is normally present, appears to play a role in regulating trophoblast invasion.

<table>
<thead>
<tr>
<th>Grade</th>
<th>Definition</th>
<th>Clinical Criteria</th>
<th>Histologic Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Grade 1:</strong> Abnormally adherent placenta (Placenta accreta)</td>
<td>At vaginal delivery: - no separation with synthetic oxytocin and gentle controlled cord traction; - attempts at manual removal of the placenta results in heavy bleeding from the placenta implantation site requiring mechanical or surgical procedures.</td>
<td>Microscopic examination of the placental bed samples from hysterectomy specimen shows extended areas of absent decidua between villous tissue and myometrium with placental villi attached directly to the superficial myometrium. The diagnosis cannot be made on just delivered placental tissue nor on random biopsies of the placental bed.</td>
<td></td>
</tr>
<tr>
<td><strong>Grade 2:</strong> Abnormally invasive placenta (Placenta Increta)</td>
<td>At vaginal delivery: - no separation with synthetic oxytocin and gentle controlled cord traction; - attempts at manual removal of the placenta results in heavy bleeding from the placenta implantation site requiring mechanical or surgical procedures.</td>
<td>Microscopic examination of the placental bed samples from hysterectomy specimen shows extended areas of absent decidua between villous tissue and myometrium with placental villi attached directly to the superficial myometrium. The diagnosis cannot be made on just delivered placental tissue nor on random biopsies of the placental bed.</td>
<td></td>
</tr>
<tr>
<td><strong>Grade 3:</strong> Abnormally invasive placenta (Placenta Percreta)</td>
<td>Further divided into Grade 3a, 3b and 3c as follows:</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Grade 3a:</strong> Limited to the uterine serosa</td>
<td>At laparotomy: abnormal macroscopic findings on uterine serosal surface (as above) and placental tissue seen to be invading through the surface of the uterus; - no invasion into any other organ, including the posterior wall of the bladder (a clear surgical plane can be identified between the bladder and uterus).</td>
<td>Hysterectomy specimen showing villous tissue within or breaching the uterine serosa.</td>
<td></td>
</tr>
<tr>
<td><strong>Grade 3b:</strong> With urinary bladder invasion</td>
<td>At laparotomy: placental villi are seen to be invading into the bladder but no other organs; - clear surgical plane cannot be identified between the bladder and uterus.</td>
<td>Hysterectomy specimen showing villous tissue breaches the uterine serosa and invading the bladder wall tissue or urothelium.</td>
<td></td>
</tr>
<tr>
<td><strong>Grade 3c:</strong> With invasion of other pelvic tissue or organs</td>
<td>At laparotomy: placental villi are seen to be invading into the broad ligament, vaginal wall, pelvic sidewall or any other pelvic organ (with or without invasion of the bladder).</td>
<td>Hysterectomy specimen showing villous tissue breaches the uterine serosa and invading pelvic tissues/organisms (with or without invasion of the bladder).</td>
<td></td>
</tr>

Detecting the placenta accreta spectrum during pregnancy is strongly recommended because the best results are achieved when delivery takes place at a maternal care facility of level III or IV before the onset of labor or bleeding, while also preventing placental disruption. Ultrasonography is the diagnostic choice.7 Most of the placenta acceata are diagnosed in the second and third trimester but can also be diagnosed in the late first trimester. Ultrasound may identify the protrusion of placental tissue beyond the outer confines of the uterine myometrium and/or increased vascularity between serosa and adjacent structures such as the bladder. Nonetheless, it is widely recognized that magnetic resonance imaging (MRI) plays a significant role in accurately diagnosing PAS, demonstrating both high sensitivity and specificity.

The accepted and practical approach to treat the placenta accreta spectrum is a cesarean hysterectomy for most low- and middle-income countries where diagnosis, follow-up and additional treatments are not available.8 Conservative management or expectant management where the placenta is left in situ after delivery of newborn with umbilical cord ligated and hysterotomy site closed followed by uterotonic drugs, compression sutures, intrauterine balloon tamponade and uterine artery embolization or ligation should be considered only for carefully selected cases of placenta accreta spectrum where resource rich expertise and facility is available.9 The multidisciplinary team includes maternal-fetal medicine specialists, anesthesiologists, neonatologists, interventional radiologists, pathologists, and blood bank and nursing personnel. The patient underwent a...
cesarean hysterectomy as it is the standard care of choice in our settings.

Placenta accreta spectrum has been rising due to increased operative procedures for the delivery of the baby. So it is important to consider diagnosis in early pregnancy for early management. In resource limited settings, cesarean hysterectomy is the best possible treatment for the patients.

CONCLUSION
Placenta accreta spectrum can be a life-threatening obstetric emergency. In rare cases it can lead to uterine rupture. Uterine rupture should be considered as a differential diagnosis in any trimester pregnancy presenting with abdominal pain especially in case of shock. Quick diagnosis and management can avoid catastrophic outcomes and decrease maternal and fetal morbidity and mortality.
